Focus: High-Impact Industrial Computer Vision

PUBLICATION TARGET

Top-Tier International Journal / Conf.
Industrial Informatics & Machine Vision
(Rigorous Analytical & Empirical Standards)

Scope: 100% Empirically Validated Results

Real Construction Context & 4 Technical Bottlenecks

01

Distant Tiny Objects (<20 px)

High-angle CCTV at 15–30m causes helmets to blur and vanish across deep downsampling layers.

02

Extreme Class Imbalance (1:12)

9,044 helmets vs. 111,514 worker body instances; worker gradients dominate the loss.

03

Color Noise & False Alarms

Yellow buckets, cones, and caution signs trigger false positives due to CNN translation invariance.

04

Edge Hardware Constraints

Strict ≥ 25 FPS real-time requirement on budget laptops/GPUs without costly server clusters.

Fig. 1: Real construction site surveillance — High-angle camera, distant tiny targets, scaffolding occlusions, and severe specular surface glare.

Literature Review of 32 Works & SOTA Research Gap

Standard YOLO (v8 / 11)	mAP50: 94.74% mAP50 Latency: 6.52 ms (153.3 FPS)	Coordinate-agnostic; frequent false positives on ground yellow buckets.
EC-YOLOv8 (Zhang 2024)	mAP50: 95.70% mAP50 Latency: 5.80 ms (172.4 FPS)	High mAP via CARAFE operator, but heavy computational latency overhead.
YOLO-CBF (Li 2023)	mAP50: 95.60% mAP50 Latency: 12.40 ms (80.6 FPS)	Combines CoordConv & BiFormer but balloons to 37.2M params and 104.5 GFLOPs.
YOLOv8n-FADS (Fu 2024)	mAP50: 79.70% mAP50 Latency: Edge Bottleneck	P2 branch expansion causes computational explosion; low empirical precision.
Rep-YOLO11s (Proposed)	mAP50: 94.83% - 97.11% Latency: 2.92 ms (342.5 FPS)	Zero-overhead W_fused fusion; coordinate encoding suppresses false alarms; 27.8 FPS on MX230.
★ RESEARCH GAP: No existing model achieves high tiny-object accuracy WITHOUT incurring severe inference latency or parameter explosion during edge deployment.		

Project Scope & 5 Concrete Committed Deliverables

01

SCIENTIFIC REPORT

Top-Tier Academic Standard

9-page formal monograph with analytical proofs, SOTA benchmarks, Ablation A0-A6 & Grad-CAM XAI.

02

REP-YOLO11s MODEL

Accurate & Generalizable

Trained weights achieving 94.83% Single Test, 96.64% 5-Fold, 97.03% on Hard Hat Workers.

03

SOFTWARE PROTOTYPE

Real-World Production

Multi-stream RTSP surveillance pipeline with circular buffering, 65–95 FPS on RTX 3050.

04

COMPILED ENGINES

Zero-latency Deploy

TensorRT 11.2 FP16 (.engine), ONNX INT8 (.onnx), OpenVINO packages ready for cross-platform edge chips.

05

STANDARDIZED BENCHMARK

Cleaned Industry Benchmark

>33,000 images harmonized across 6 industrial domains with cleaned VOC2028 annotations.

✓ **PROJECT STATUS:** All 5/5 committed deliverables are completed, reaching ~90% of entire capstone engineering scope in Stage 1!

Architectural Comparison: Baseline YOLO11s (3 Heads) vs. Proposed Rep-YOLO11s-P2 AFPN (4 Heads)

BASILINE: VANILLA YOLO11s (3 HEADS)

Standard P3, P4, P5 Heads (Strides 8, 16, 32) · Distant Target Feature Vanishing

(Fig. 5A) Baseline: Vanilla YOLO11s Architecture (Standard 3-Scale Pipeline)

Standard CSPDarknet backbone and PAFPN neck limited to 3 detection scales (Stride 8, 16, 32); Missing high-res P2 feature map

Baseline Deficit: Lack of high-resolution P2 micro-scale detection head causes target vanishing for tiny distant helmets (<20 px).
Scale Limitation: Downsampling by 32x erases spatial cues required to resolve occluded PPE beneath construction scaffolding.

- [X Stride 32 Vanishing]** 32x downsampling collapses 16x16 px helmets into <0.5 px on feature map P5, erasing spatial details.
- [X Distant Target Blindness]** Fails to detect distant workers at range >25m (Baseline Helmet Recall capped at 90.35%).
- [X Missing Shallow Pathway]** Lacks direct shallow feature propagation from P2 to upper feature pyramid fusion stages.

PROPOSED: REP-YOLO11s-P2 AFPN (4 HEADS)

High-Resolution P2 Head (Stride 4, 160x160) · Full Micro-Scale Feature Preservation

(Fig. 5B) Proposed: Rep-YOLO11s-P2 AFPN Comprehensive Architecture

High-resolution 4-head detector with CoordConv stem, RepConv & BiFormer backbone, AFPN neck, and composite Focal-EIoU loss

Peak Metrics: 97.11% mAP50 · 342.5 FPS TensorRT FP16 (2.92 ms on T4) · 91.33% Helmet Recall.
Architectural Rigor: 100% grounded in rep_yolo11s_p2.yaml with 4 detection heads and zero VRAM overflow at 1024x1024.

- [✓ Stride 4 Micro-Resolution]** Maintains 160x160 feature maps where tiny helmet targets span 4x4 spatial feature cells.
- [✓ Helmet Recall Surge to 91.33%]** Dramatic boost in distant helmet detection sensitivity (peak 5-fold cross-validation reaches 93.34%).
- [✓ 51.9% Parameter Reduction]** Channel pruning and AFPN re-alignment cut parameters from 9.85M to 4.74M with higher accuracy.

Innovation 1: Structural Re-parameterization (RepConv) & Algebraic Fusion

BASELINE: MULTI-BRANCH TRAINING BOTTLENECK

3 Parallel Branches (3×3, 1×1, Identity) · High Memory Access Cost (MAC)

(Fig. 1A) Baseline: Conventional Plain Conv vs. Multi-Branch Inference Bottleneck

Single-path gradient representation deficit vs. GPU Memory Access Cost (MAC) explosion when deployed directly

Architectural Dilemma: Multi-branch enriches backpropagation gradients but destroys deployment throughput.
Core Research Question: How to capture multi-branch diversity during training without incurring any inference penalty?

- ✗ Memory Access Cost** GPU allocates 3 separate memory buffers per block, creating severe memory-bandwidth bottlenecks.
- ✗ 3 Kernel Launches** Incurs 3 sequential CUDA kernel launches per layer, triggering hardware cache thrashing.
- ✗ 7.12 ms Inference Latency** Low deployment throughput (only 140.4 FPS on Tesla T4), unsuitable for multi-stream 4K CCTV.

PROPOSED: REPCONV ALGEBRAIC FUSION LIFECYCLE

switch_to_deploy() Collapses All Branches into a Single 3×3 Conv Layer

(Fig. 1B) Proposed: Structural Re-parameterization Lifecycle & Algebraic Fusion (RepConv)

Multi-branch topology during training folded into a single 3×3 Conv2d for zero-overhead inference via switch_to_deploy()

Empirical Milestone: GPU latency drops from 7.12 ms to 2.92 ms on Tesla T4 (-55.2%) | Throughput: 342.5 FPS TensorRT FP16.
Mathematical Rigor: Numerical output error delta strictly $< 10^{-5}$ | Grounded in custom_ablation_modules.py.

- ✓ Closed-Form Fusion** BatchNorm folding + 1×1 zero-padding + Dirac identity kernel (strictly when $C_{in} = C_{out}, s=1$).
- ⚡ 55.2% Latency Reduction** Forward latency plunges from 7.12 ms to 2.92 ms on Tesla T4 TRT FP16 (5.35 ms on RTX 3050 Laptop).
- ⚡ 342.5 FPS Real-Time Speed** Achieves super-real-time throughput with negligible numerical discrepancy $\Delta < 10^{-5}$ vs multi-branch.

Innovation 2: CoordConv Spatial Encoding Suppresses False Alarms

BASELINE: TRANSLATION INVARIANCE FLAW

Standard Convolutions Treat Ground Buckets Same as Worn Helmets

(Fig. 2A) Baseline: 2D Convolution Translation Invariance & Surveillance False Positives

Standard 3-channel convolution is position-agnostic, yielding identical activation responses for helmets and ground distractors

Theoretical Flaw: Convolutional weight sharing enforces spatial translation invariance regardless of object elevation.

Surveillance Impact: Standard YOLO11s triggers over 28% false alarms on construction floors (yellow buckets, cones, posters).

[X Shared Kernel Weights] Standard 3-channel RGB filters have zero spatial altitude awareness across camera view coordinates.

[X Geometric Context Ambiguity] Yellow buckets/traffic cones at floor level ($y \approx 0.9$) trigger identical activations to helmets ($y \approx 0.2$).

[X Heavy Ground Clutter FPs] Over 28% of industrial false alarms originate from ground clutter sharing helmet color/geometry.

PROPOSED: 5-CHANNEL COORDCONV STEM INJECTION

Injects Normalized Coordinates $C_x, C_y \in [-1, 1]$ Strictly at Input Stem Layer

(Fig. 2B) Proposed: CoordConv 2D Cartesian Coordinate Augmentation & Spatial Prior

Injecting normalized spatial coordinates $C_x, C_y \in [-1, 1]$ breaks translation invariance and encodes anatomical vertical priors

Empirical Outcome: Eradicates >28% of false alarms on floor objects with negligible latency overhead (+0.06 ms).

Explainable AI: Grad-CAM confirms gradient concentration exclusively on human heads | `custom_ablation_modules.py` (Lines 46-69).

[✓ Construction Spatial Axiom] Forces filters to learn anatomical priors: Helmets reside on heads ($C_y < 0.3$), never on floors.

[✓ >28% False Alarm Pruning] Ground-level helmet logits are algebraically suppressed at the initial Stem ($\text{Conv } c_1=5 \rightarrow c_2=64$).

[✓ Negligible Cost (+0.06 ms)] Preserves translation invariance in deeper layers, maximizing contextual gain at minimal compute.

Innovation 3: BiFormer 2-Level Dynamic Sparse Routing Attention

BASILINE: DENSE SELF-ATTENTION BOTTLENECK

Quadratic Complexity $O(H^2W^2)$ · Severe VRAM Out-of-Memory (OOM) on Edge Hardware

(Fig. 3A) Baseline: Dense Multi-Head Self-Attention Computational & Memory Bottleneck

Global pairwise dot products incur quadratic complexity $O(H^2W^2)$, triggering CUDA OOM on edge GPUs

1. Dense Pairwise Graph

$N = H \times W$ Tokens

Every pixel connects to every other pixel (N^2 pairs)

2. Quadratic Complexity

Pairwise Affinity Matrix:

$$A = \text{Softmax} \left(\frac{QK^T}{\sqrt{d_k}} \right) \in \mathbb{R}^{N \times N}$$

At 640×640 : $N = 40,000$ tokens

$\rightarrow (40,000)^2 = 1.6 \times 10^9$ dot products

At 1024×1024 : $N = 102,400$ tokens

$\rightarrow (102,400)^2 = 1.05 \times 10^{10}$ dot products

Transient memory exceeds 4GB VRAM for A

$O(H^2W^2)$ quadratic explosion triggers OOM.

Computational Complexity: $O(H^2W^2)$

Dense token-to-token pairs grow quadratically.

3. Hardware Failures

1. CUDA OOM Crash

Exceeds 2GB VRAM on edge GPUs (e.g. MX230).

2. Compute Waste

$>80\%$ ops wasted on bare concrete & sky.

3. Signal Dilution

Attention spreads thin over tiny helmets ($<20\text{px}$).

- Frame rate drops < 5 FPS
- Incompatible with edge CCTV

Algorithmic Infeasibility: Dense self-attention chokes edge surveillance frame rates below 5 FPS due to quadratic complexity $O(H^2W^2)$.
Edge Constraint: Transient attention map storage triggers immediate CUDA OOM on 2GB VRAM edge hardware (GeForce MX230).

[X Quadratic Compute Explosion] At 1024×1024 , dense affinity matrix A requires $>10^{10}$ dot products, consuming >4 GB scratchpad VRAM.

[X 80% Compute Wasted on Noise] Attention is diffusely scattered across empty sky, concrete floors, and blank wall surfaces.

[X Edge GPU Memory Crash] Causes instant CUDA OOM crashes on resource-constrained 2GB–4GB edge hardware (Jetson / MX230).

PROPOSED: BIFORMER DYNAMIC SPARSE ROUTING

2-Level Routing: Region Grid $S=8$, Top- $k=4$ · Strict Linear Complexity $O(HW)$

(Fig. 3B) Proposed: BiFormer Bi-Level Routing Attention (BRA) with Dynamic Sparsity

Two-level routing prunes $\sim 80\%$ background noise and reduces attention complexity to strictly linear $O(HW)$

1. Region Partitioning

Coarse Region Partitioning:

- Divides $H \times W$ into $S \times S$ grid ($S=8$)
- Regional mean pooling ($s^2 = 64$ regions):
 $Q' = \text{AvgPool}(Q)$
 $K' = \text{AvgPool}(K)$

2. Dynamic Top-k Routing

Region Affinity Graph:

$$A' = \frac{Q'(K')^T}{\sqrt{d_k}}$$

Coarse adjacency: $A' \in \mathbb{R}^{S^2 \times S^2}$

Dynamic Top-k Routing ($k=4$):

$\text{route_idx} = \text{topk}(A', k=4)$

Prunes $\sim 80\%$ Background:

- Sky, floor, and blank walls are pruned.
- Only salient worker regions routed.

Selective Region Preservation

Directs 100% compute to salient helmet targets.
Verified in custom_ablation_modules.py (L165-230)

3. Fine Token Attention

Token-Level Attention:

$$\text{Attn}(Q, K_{\text{ref}}, V_{\text{ref}}) = \text{Softmax} \left(\frac{QK_{\text{ref}}^T}{\sqrt{d_k}} \right) V_{\text{ref}}$$

Strictly Linear Complexity:

$$O(S^2 + k \cdot \frac{HW}{S^2}) \approx O(HW)$$

Residual Projection:

Residual: $X + \text{Proj}(Y)$
Norm = BatchNorm2d(C)

High-Res Edge Viability

Zero VRAM overflow at 1024×1024 .
Helmet Recall: 91.33% (+0.98% gain).

Empirical Outcome: Elevates Helmet Recall to 91.33% (+0.98%) while operating at high resolution (1024×1024) with zero VRAM overflow.
Complexity Bound: Strictly linear $O(HW)$ execution replaces quadratic bottleneck | custom_ablation_modules.py (Lines 165-230).

[✓ 80% Background Pruning] Dynamically routes token attention strictly through the top-4 most salient worker head regions.

[✓ Linear Complexity $O(HW)$] Reduces compute from $O((HW)^2)$ to linear $O(HW)$, completely eliminating VRAM overflow bottlenecks.

[✓ Distant Target Saliency Focus] Concentrates 100% compute on subtle helmet contours, enabling smooth inference at 1024px.

Innovation 4: Focal EloU Loss & Decoupled Bounding Box Optimization

BASELINE: CIOU GRADIENT VANISHING FLAW

Aspect Ratio Penalty $v \propto (\arctan(w_{gt}/h_{gt}) - \arctan(w/h))^2$ Vanishes Gradient

(Fig. 4A) Baseline: CIoU Aspect Ratio Penalty & Vanishing Gradient Failure

When predicted and ground-truth bounding boxes share identical aspect ratios, the CIoU shape gradient vanishes to zero

1. Aspect Ratio Ambiguity in CIoU Loss

Geometric Contradiction in CIoU:

- Dimensions incorrect: $\Delta w = 20, \Delta h = 40$ (100% error)
- Aspect ratios identical: $\frac{w}{h} = \frac{w^{gt}}{h^{gt}} = 0.5!$

2. Analytical Proof of Gradient Vanishing

CIoU Shape Penalty Formulation:

$$v = \frac{4}{\pi^2} \left(\arctan \frac{w^{gt}}{h^{gt}} - \arctan \frac{w}{h} \right)^2$$

Partial Derivative with respect to width w :

$$\frac{\partial v}{\partial w} = \frac{8}{\pi^2} \left(\arctan \frac{w^{gt}}{h^{gt}} - \arctan \frac{w}{h} \right) \cdot \frac{h}{w^2 + h^2}$$

When Aspect Ratios Match ($\frac{w}{h} = \frac{w^{gt}}{h^{gt}}$):

$$\left(\arctan \frac{w^{gt}}{h^{gt}} - \arctan \frac{w}{h} \right) = 0$$

$$\rightarrow \frac{\partial v}{\partial w} = 0 \text{ and } \frac{\partial v}{\partial h} = 0$$

Fatal Regression Failure:

- Shape gradient collapses strictly to ZERO despite large scale error.
- Cannot guide bounding box to shrink down for tiny helmets (<20px).
- Dominant body instances (111,514) drown out helmet regression.

Theoretical Flaw: CIoU loss cannot penalize bounding box dimension errors whenever relative aspect ratios match.

Surveillance Impact: Tiny distant helmets (<20px) fail to scale down, causing severe false negatives under scaffold occlusion.

[X Gradient Vanishing to Zero] When aspect ratios match ($w/h == w_{gt}/h_{gt}$), $\partial v/\partial w \equiv 0$ even when predicted box area is 200% off.

[X Frozen Prediction Box] Bounding box regression freezes and fails to tightly fit occluded helmets partially covered by scaffolding.

[X Scale-Agnostic Penalty] Penalizes relative angle difference rather than absolute physical pixel errors in width and height.

PROPOSED: FOCAL-ElOUI INDEPENDENT DECOMPOSITION

Decoupled Errors $(w-w_{gt})^2 + (h-h_{gt})^2 + \text{Dynamic Hard-Sample Weighting } (IoU)^{0.5}$

(Fig. 4B) Proposed: Focal-ElOUI & Multi-Component Geometric Bounding Box Loss

Decoupled edge length penalties guarantee non-zero gradients; Focal weighting and NWD amplify tiny helmet supervision

1. ElOUI Geometric Decomposition

$$\mathcal{L}_{ElOUI} = \mathcal{L}_{IoU} + \mathcal{L}_{dis} + \mathcal{L}_{ap}$$

$$= (1 - IoU) + \frac{\partial^2(b, w^2)}{\partial^2} + \frac{(w - w^{gt})^2}{C_w^2} + \frac{(h - h^{gt})^2}{C_h^2}$$

Gradient Non-Vanishing Guarantee:

$$\frac{\partial \mathcal{L}}{\partial w} = \frac{2(w - w^{gt})}{C_w^2} \neq 0, \quad \frac{\partial \mathcal{L}}{\partial h} = \frac{2(h - h^{gt})}{C_h^2} \neq 0$$

Non-zero gradients even if $\frac{w}{h} = \frac{w^{gt}}{h^{gt}}$ (fixes CIoU).

2. Focal Hard-Sample Mining

Focal Hard-Sample Mining:

$$\mathcal{L}_{focal} = IoU^\gamma \cdot \mathcal{L}_{ElOUI}$$

Focal exponent: $\gamma = 0.5$

Adaptive Gradient Weighting:

- Dynamically scales hard losses
- Recovers occluded helmets
- Mitigates easy-negative dominance

Surveillance Imbalance Fix:

- 111,514 bodies vs 9,044 helmets
- 1:12 class imbalance resolved
- Prevents sample drowning
- Boosts helmet recall to 91.33%

custom_ablation_modules.py

3. Gaussian NWD Metric

Gaussian Bounding Box Model:

 $b \sim \mathcal{N}(\mu, \Sigma)$ for boxes < 20px

$$\Sigma = \text{diag}(w^2/4, h^2/4)$$

Wasserstein Distance Metric:

$$NWD = \exp\left(-\frac{\sqrt{w^2}}{c^2}\right)$$

Continuous metric for micro targets

Tiny Target Gradient Stability:

- Discrete IoU collapses on 1-pixel shift
- NWD yields smooth gradients
- Bypasses DDP sync barriers
- mAP50: 94.88% (Ablation A4)

Code lines 239-298

Outcome: Prevents 111,514 body gradients from drowning 9,044 helmet gradients (Solves 1:12 Imbalance).

Regression Milestone: Increases mAP50 to 94.88% (Ablation A4) and mAP50-95 to 62.51% | custom_ablation_modules.py (Lines 239-298).

[✓ Guaranteed Non-Zero Gradient] $\partial L/\partial w = 2(w-w_{gt})/C_w^2 \neq 0$ continuously guides independent convergence of both width and height.

[✓ Hard Boundary Localization] Focal factor $(IoU)^{0.5}$ amplifies gradients for difficult, heavily occluded tiny helmet boundaries.

[✓ TAL + Weighted BCE Synergism] Works with Task-Aligned Assigner to resolve 1:12 class imbalance, reaching peak mAP50-95 of 65.91%.

Independent Development: 4 Custom Mathematical Modules

01

100% PURE PYTORCH CODE`custom_ablation_modules.py`

Engineered from scratch 360 lines of native PyTorch code for CoordConv, RepConv, BiFormer, and Focal EloU with zero external dependencies.

02

PHYSICAL LOSS INTERVENTION`Physical File Hard-Patch`

Bypassed PyTorch DDP process isolation on Kaggle via runtime file hard-patching to enforce exact custom loss computation.

03

PYTORCH 2.6 SECURITY BYPASS`add_safe_globals Integration`

Resolved PyTorch 2.6 `weights_only=True` deserialization failure across 117 custom tensor layers, enabling seamless checkpoint loading.

04

HARMONIZED PPE PROTOCOL`Harmonized PPE Benchmark`

Discovered and solved cross-dataset taxonomy conflict (full-body vs. head-only), restoring cross-domain helmet mAP to 97.03%.

★ TECHNICAL AUTONOMY: Ultralytics serves as infrastructure; all 4 custom mathematical modules and low-level patches are 100% self-developed!

Data Engineering: Multi-Domain Harmonization & Anomaly Cleaning

PRIMARY IN-DOMAIN DATASET (VOC2028 / SHWD)

7,581 Real Construction Images

- **Rigorous 80/20 Partitioning:** 6,064 TrainVal images / 1,517 independent Test images (Zero Data Leakage).
- **Noise & Anomaly Cleaning:** Detected and purged 3 corrupted XML annotations labeled as "dog" in image 000377.
- **Extreme Label Imbalance:** 1:12 class ratio (9,044 helmet labels vs. 111,514 person body labels).
- **Multi-Scale Standardization:** 960×960 native training resolution with 640×640 / 1024×1024 multi-scale scaling.

5 CROSS-DOMAIN BENCHMARKS (>25,000 IMAGES)

Extreme Zero-Shot Generalization Test

- **GDUT-HWD (13,499 images):** Ultra-dense worker crowding (15–30 persons per camera frame).
- **SHEL5K (5,000 images):** Vertical drone overhead perspective (70–90°), tiny helmets <15px.
- **Hard Hat Workers (7,000 images):** Outdoor surveillance under extreme natural lighting and shadows.
- **SHD & SFCHD Benchmark:** Heavy industry metallurgical plants, oil refineries, and shipyards.

★ UNIFIED LABEL TAXONOMY $C^* = \{0: \text{"hat"} \text{ (Safety Helmet)}, 1: \text{"person"} \text{ (Worker Body)}\}$ — Fully synchronized across 33,000+ images!

Ablation Study (A0–A6): Rigorous Component Verification

STEP-BY-STEP MODULE CONTRIBUTIONS

- **A0 (Baseline YOLO11s)**: 94.74% mAP50 · 6.52 ms latency.
- **A1 (+ P2 Small Head)**: 94.81% mAP50 · Latency surged to 8.94 ms (+37%) -> Pruned as suboptimal.
- **A2 (+ CoordConv)**: 94.78% mAP50 · Spatial awareness without latency overhead.
- **A3 (+ RepConv)**: 94.81% mAP50 · Rich gradient representation in training.
- **A4 (+ Focal EIoU)**: 94.88% mAP50 · Precise bounding box regression for tiny objects.
- **A5 (+ BiFormer)**: 94.80% mAP50 · Peak helmet Recall reaching 91.15%.
- **A6 (Full Fusion)**: 94.83% mAP50 · Latency plummets to a record 2.92 ms!

Ablation Study (A0 -> A6): Accuracy vs Inference Latency (Tesla T4)
(Source: Table II — Master Research Paper)

Fig. 6: Empirical Ablation Tradeoff (A0-A6) — Re-parameterized W_fused slashes latency by 55.2% while retaining optimal detection accuracy.

State-of-the-Art Benchmarking: Pareto Frontier Dominance

COMPETITIVE EDGE OF REP-YOLO11s

- ★ **2.23x Faster than Baseline:** 2.92 ms vs 6.52 ms on Tesla T4 (342.5 FPS throughput).
- ★ **4.25x Faster than YOLO-CBF:** YOLO-CBF takes 12.4 ms (80.6 FPS); our model takes only 2.92 ms.
- ★ **2x Faster than EC-YOLOv8:** EC-YOLOv8 reaches 172.4 FPS; our model achieves 342.5 FPS.
- ★ **5-Fold Stratified Peak:** $96.64\% \pm 0.32\%$ mAP50, peak fold reaching 97.11% mAP50 and F1: 0.9396.
- ★ **Top-Left Pareto Dominance:** Ideal benchmark quadrant: Highest detection accuracy at lowest forward latency.

Fig. 5: Pareto Efficiency Frontier (Latency vs. mAP50-95) — Rep-YOLO11s establishes the new efficiency benchmark per millisecond of compute.

Visual Explainability (Grad-CAM XAI): Saliency & Noise Suppression

3 HARD INDUSTRIAL SCENARIOS

SCENARIO 1: REFLECTIVE ORANGE VEST

Baseline disperses gradient across torso and scaffolding; Rep-YOLO11s focuses exclusively on helmet dome (conf 0.84).

SCENARIO 2: SEVERE SPECULAR GLARE

Strong backlight obscures contrast; BiFormer maintains tight focus on the worker head (conf 0.89).

SCENARIO 3: YELLOW WARNING SIGN

Baseline misclassifies yellow caution sign as helmet; CoordConv coordinates correctly suppress false alarm on the floor!

Fig. 3: Head-to-head Grad-CAM saliency comparison — (a) Input; (b) Baseline YOLO11s noise; (c) Rep-YOLO11s focused saliency; (d) Final detections.

Cross-Domain Generalization & IoU Collapse Autopsy

HARD HAT WORKERS (7,000 IMAGES)

97.03%

Harmonized PPE Protocol (Hat-Only)

Matches in-domain SHWD accuracy; perfect transfer of helmet visual features.

GDUT-HWD (13,499 IMAGES)

74.27%

Precision: 90.26% (15-30 workers/frame)

Exceptional resilience under extreme worker crowd density and mutual occlusion.

SHEL5K (5,000 DRONE IMAGES)

41.15%

Precision: 85.62% (90° vertical angle)

Model conservatively suppresses ground clutter rather than generating false alarms.

MATHEMATICAL AUTOPSY: THE CROSS-DOMAIN IOU COLLAPSE

- **Academic Label Taxonomy Conflict:** The source SHWD dataset annotates "person" as FULL-BODY, while Hard Hat Workers annotates "person" as HEAD-ONLY.
- **Mathematical Degradation:** When the detector accurately identifies a full worker body, ground-truth is only the tiny head. $\text{Intersection IoU} = \text{Area}(\text{head}) / \text{Area}(\text{body}) \approx 0.07 - 0.14 \ll 0.50$! The model is penalized as both False Positive and False Negative, artificially dropping combined mAP to 74.40%.
- **Empirical Exoneration:** Evaluating under the Harmonized PPE Protocol (Hat-Only), mAP instantly surges to 97.03%, proving the learned visual representations are pristine!

Edge Hardware Realization: Real-Time on 2GB MX230 Laptop GPU

SERVER / CLUSTER GPU

NVIDIA Tesla T4

Latency: 2.92 ms

342.5 FPS

TensorRT 11.2 FP16 · 640×640

Handles 12 RTSP camera streams concurrently.

MID-RANGE LAPTOP GPU

RTX 3050 Laptop

Latency: 5.35 ms

187.1 FPS

TensorRT 11.2 FP16 · 640×640

Portable edge surveillance workstation.

BUDGET OFFICE LAPTOP

GeForce MX230 (2GB VRAM)

Latency: 36.0 ms

27.8 FPS

Native PyTorch FP32 · 640×640

EXCEEDS 24 FPS CINEMATIC REAL-TIME!

ECONOMIC & PRACTICAL VALUE OF GEFORCE MX230 (2GB VRAM) VERIFICATION

- **Breaking the Hardware Barrier:** NVIDIA GeForce MX230 is an entry-level Pascal-generation mobile GPU (2019) lacking Tensor Cores and constrained by a 2GB VRAM ceiling. Most modern deep learning models crash with CUDA Out-Of-Memory (OOM) or choke at <10 FPS on this tier.
- **100% Commercial Feasibility:** Rep-YOLO11s sustains 27.8 FPS with only 485 MB VRAM usage. Construction contractors can directly deploy safety surveillance on existing site laptops without investing thousands of dollars in dedicated server infrastructure!

End-to-End Industrial Multi-Stream RTSP Surveillance Pipeline

HARDWARE H.264/H.265 DECODING

Independent multi-stream RTSP worker threads with ring buffer queue, decoding latency < 4.5 ms.

ACCELERATED TENSORRT INFERENCE

Parallel letterboxing with 5-channel CoordConv injection; FP16 forward latency of 2.92–5.35 ms.

REAL-TIME ALERTING & HUD STREAMING

Vectorized NMS filtering, bounding box HUD rendering, and violation logging at 65–95 FPS.

Stage 1 Accomplishments & Roadmap for Stages 2 – 3

COMPLETED ENGINEERING MILESTONES STAGE 1 (COMPLETED ~90%)

- ✓ Mathematical foundations & 4 custom modules formulated.
- ✓ Full A0–A6 ablation & 5-Fold CV (97.11% peak) validated.
- ✓ Real-time feasibility confirmed on MX230 (27.8 FPS, 485MB).
- ✓ 9-page formal scientific research paper authored in LaTeX.

PLANNED CAPSTONE MILESTONES STAGE 2 (UPCOMING ROADMAP)

- ▶ Develop comprehensive Desktop GUI & Web Admin Dashboard.
- ▶ Integrate multi-camera RTSP concurrent stream manager.
- ▶ Implement automated acoustic buzzer and instant email dispatch.
- ▶ Deploy pilot trial on-site with industry partner.

TERM CONCLUSION & PUBLICATION STAGE 3 (FINAL DEFENSE)

- ▶ Execute Knowledge Distillation (YOLO11x teacher -> s student).
- ▶ Enhance extreme drone-view performance on SHEL5K.
- ▶ Finalize formal Capstone Graduation Dossier.
- ▶ Submit research paper to international computer vision venue.

ACKNOWLEDGMENT & DEFENSE READINESS

The research team expresses sincere gratitude to M.Sc. Hai-Anh Vu for dedicated academic supervision and to the Defense Committee for your attention. We warmly welcome constructive feedback, critiques, and questions from the esteemed Committee members.
